

# From Hiro Nakayama-san

Wild injection  
↓

HV state	Normal injection	Continuous injection	Expected BG level
“STANDBY” or “OFF”	Allow	Allow	Higher (w/ wild injection BG)
“PEAK”	Inhibit	Allow	Nominal (w/ injection BG)
Other transient states “PREPARING”, “TURNINGOFF”, “RAMPINGUP”, “RAMPINGDOWN”, “TRIP”, “ERROR”, “UNKNOWN”	Inhibit	Inhibit	Lower (no injection BG)

1. Accumulate beam current with normal (wild) injections
2. SKB announces PHYSICS\_READY
3. Belle shift starts HV ramp-up
4. After HV becomes PEAK, SKB can start continuous injections

**Question: What HV value will be appropriate for RPC as “standby”? What was the value at Belle?**

**The standby values for RPC might be needed to adjust according to reality. For instance, if the HV trips happen seriously during beam injections.**

**For MPPC, it is more simple, we can apply zero or PEAK values for standby. Should be fine.**
