## Projectile Motion

## Morgyn Stryker 5/4/2011

Figure 1: Typical mortar used, 10 inch barrel [1].

This project will evaluate the motion, through air near the earth's surface, of a solid bomb projectile from a mortar using gun powder as the ballistic source .

The mass of black powder needed can be calculated from the initial velocity required to hit the target at the set elevation angle and calculated target angle. The mass is determined based on the chemical energy needed to achieve the initial velocity.

$$
\begin{aligned}
\mathrm{d} U & =C_{v} d T & & \text { Equation } 1 \\
\mathrm{~W} & =\mathrm{pdV} & & \text { Equation } 2
\end{aligned}
$$

Must make many assumptions in approach.

Gunpowder, or black powder, is composed of potassium nitrate, charcoal, and sulfur in an 84:8:8 ratio [2]. The ideal reaction for this combustion is:

$$
10 \mathrm{KNO}_{3}+8 \mathrm{C}+3 \mathrm{~S} \rightarrow 2 \mathrm{~K}_{2} \mathrm{CO}_{3}+3 \mathrm{~K}_{2} \mathrm{SO}_{4}+6 \mathrm{CO}_{2}+5 \mathrm{~N}_{2}
$$

An estimation of the heat released is $685 \mathrm{kcal} / \mathrm{kg}$, the volume expansion factor is 5100 , and the density is about $1.04 \mathrm{~g} / \mathrm{cc}[2]$.

## Method

```
Basic code taken from previous assignment:
double ODE::RHS_f(double \(t\), double f[], double rhsf[] )\{
    // Projectile Motion Equations
    \(\operatorname{rhsf}[0]=\mathrm{f}[1] ; \quad / / \mathrm{x}\) position, due east
    rhsf[1] \(=-\mathrm{b}^{*}(\mathrm{f}[0]+\text { windx })^{*} \mathrm{~V}\); // Vx
    rhsf[2] \(=\mathrm{f}[3] ; \quad / /\) y position, due north
    rhsf[3] = -b*(f[2] + windy)*V; // Vy
    \(\operatorname{rhsf}[4]=\mathrm{f}[5] ; \quad / / \mathrm{z}\) position, height
    rhsf[5] = -b*(f[4])*V - Gravity; // Vz
\(\}\)
for(int i \(=0\); i < array; \(\mathrm{i}++\) ) \{
    P1.RK2(t, dt, f_t, N); // Implements method
    t += dt;
    if (f_t[4] < targetZ) break;
    \}
    cout << " In Try: \n Initial Velocity: " << InitialVelocity <<
end;
    cout << " Initial Angle to Target: " << InitialTheta*180/M_PI
<< endl;
```

## Simulation/Results

"RK2.dat" using 2:3:4-

$>$ How does one ensure proper simulation?
$\Rightarrow$ Do the assumptions make a large difference?
$>$ Final point determination?
$>$ Efficiency of simulation approach?
> Is an initial guess the best approach?
